

Customers Table:

FD = { CustomerID \rightarrow Fullname, Email, Passwordhash, PhoneNumber, CustomerAddress, CreationDate

Email \rightarrow CustomerID, Fullname, Passwordhash, Phonenumner, CustomerAddress, Creationdate }

Candidate Keys come out to be CustomerId and Email.

Hence, this table is in BCNF. (L.H.S. must be a SK).

Products Table:

FD = { ProductID \rightarrow Productname, Productdescription, Category, Price, Stock, ImageURL, Addedat

Productdescription \rightarrow ProductID, Productname, Category, Price, Stock, ImageURL, Addedat }

Candidate Keys come out to be ProductID and ProductDescription.

Thus, table is in BCNF. (L.H.S. are SKs).

Orders Table:

FD = { OrderID \rightarrow CustomerID, Orderdate, TotalAmount, Orderstatus }

The only candidate key is OrderID.

Table is in BCNF.

Orderdetails Table:

$$FD = \{ \text{OrderDetailID} \rightarrow \text{OrderID}, \text{ProductID}, \text{Quantity}, \text{Price} \\ (\text{OrderID}, \text{ProductID}) \rightarrow \text{Quantity}, \text{Price}, \text{OrderDetailsID} \}$$

OrderDetailID is a valid CK.

As the pair of OrderID with ProductID is always unique (as quantity is there, so these values will never repeat), this pair also becomes a valid CK.

Hence, table is in BCNF.

Admins Table:

$$FD = \{ \text{AdminID} \rightarrow \text{Username}, \text{Passwordhash} \\ \text{Username} \rightarrow \text{AdminID}, \text{Passwordhash} \}$$

AdminID and Username are both CKs.

Hence, table is in BCNF.

Stocks Table:

$$FD = \{ \text{ID} \rightarrow \text{ProductID}, \text{AdminID}, \text{Quantity} \\ (\text{ProductID}, \text{AdminID}) \rightarrow \text{Quantity}, \text{ID} \}$$

ID is a CK.

(ProductID, AdminID) is a valid CK because this pair will be unique as Quantity is added to the table. Hence, can define all the attributes.

Thus, table is in BCNF.

Payments Table:

FD = { $\text{PaymentID} \rightarrow \text{OrderID}, \text{PaymentMethod}, \text{PaymentStatus}, \text{TransactionDate}$
 $\text{OrderID} \rightarrow \text{PaymentID}, \text{PaymentMethod}, \text{PaymentStatus}, \text{TransactionDate}$ }

PaymentID is a valid CK.

OrderID is not a valid CK because it is not unique.

The table is in 3NF as R.H.S. has prime attribute (PaymentID).

Need to convert it from 3NF to BCNF.

R1 (OrderID, PaymentID)

FD = { $\text{PaymentID} \rightarrow \text{OrderID}$ }

PaymentID is CK.

Table is in BCNF.

We should call

R1 (Payments).

R2 (OrderID, PaymentMethod,
PaymentStatus, TransactionDate)

FD = { $\text{OrderID} \rightarrow \text{PaymentMethod},$
 $\text{PaymentStatus}, \text{TransactionDate}$ }

The OrderID is CK.

Table is in BCNF.

We should call

R2 (PaymentInfo).

Returns Table:

FD = { $\text{ReturnID} \rightarrow \text{OrderDetailID}, \text{Reason}, \text{ReturnStatus}, \text{RequestDate}$
 $\text{OrderDetailID} \rightarrow \text{ReturnID}, \text{Reason}, \text{ReturnStatus}, \text{RequestDate}$ }

ReturnID is a CK.

OrderDetailID is not a CK as it is not unique.

The table is in 3NF as R.H.S. has prime attribute (ReturnID).

We need to decompose table into further tables.

R1 (OrderDetailID, Reason,
ReturnStatus, RequestDate)

FD = { OrderDetailID \rightarrow Reason, ReturnStatus,
RequestDate }

CK is OrderDetailID.

It is in BCNF.

Name R1 as ReturnInfo.

R2 (ReturnID, OrderDetailID)

FD = { ReturnID \rightarrow OrderDetailID }

CK is ReturnID.

It is in BCNF.

Name R2 as Returns.
